Running Form Analysis

testvid7sec.mp4 27 March 2026

You've got a solid forefoot strike and a genuinely promising base to work with — address that vertical bounce and get your lean dialled in, and you'll unlock a seriously efficient stride at this pace.

Fair Quality

Biomechanics

3 gait cycles detected

Forefoot Strike
high confidence · 4 contacts analyzed

Foot placement high	0.04	Moderate	
Range: -0.02 – 0.04 at default range			relative to hip
Trunk lean high	2.1°	Significant	
Range: 6.0° – 10.0° at default range			from ankles (good)
Vertical oscillation high	17.7%	Significant	
Range: 0.0% – 4.5% at default range			% of body height

ASYMMETRY

Contact time

What's going well

- ✓ Arms are held compact and close to the body with a reasonable bend at the elbow. No crossing of the midline is visible, which helps maintain rotational efficiency.
- ✓ You're landing on the forefoot consistently across all frames — a real strength at this pace that reduces impact transient compared to heel striking.
- ✓ Head is neutral and gaze is directed forward — no chin-jutting or excessive neck tension visible across the frame sequence.

Focus areas

- → Vertical Oscillation
- → Trunk Lean
- → Overstriding & Foot Strike
- → Stride Asymmetry

Your Fix Plan 4 drills

Vertical Oscillation Critical

Your vertical oscillation is measured at 17.7% of body height — dramatically above the target of under 4.5% at this pace. You're spending enormous energy bouncing upward instead of driving forward, which is the single biggest efficiency drain in your current form.

`Measured: 17.7% body height` `Reference: < 4.5% body height at tempo pace`

DRILL Low Horizontal Bounds Intermediate

This drill trains your legs to push backward and horizontally rather than vertically, directly retraining the movement pattern causing your excessive bounce.

Trains forward propulsion rather than upward bounce, reducing vertical oscillation.

Step-by-step instructions

Watch drill

Trunk Lean Critical

Your trunk is only 2.1° forward — well below the 8–12° ideal for your 5:00/km pace. The good news: the lean originates from your ankles, not your waist, meaning your spine alignment is sound — but you're not using gravity to assist forward propulsion, forcing your legs to do all the work.

Measured: 2.1° forward lean Reference: 8–12° at tempo pace

DRILL Wall Lean Drill Beginner

This drill teaches you to fall forward from the ankles at the correct angle, building the proprioceptive feel for the lean you're currently missing.

Teaches the correct forward lean from the ankles — not the waist.

Step-by-step instructions

Watch drill

Overstriding & Foot Strike Moderate

Your foot contacts the ground 0.039 ahead of your hip — just inside the moderate overstriding threshold at this pace — combined with a forefoot strike, which does reduce the impact transient. However, the forward foot placement still creates a mild braking force on each stride that, combined with your upright posture, is associated with increased load on the knee and hip.

Measured: 0.039 ahead of hip Reference: < 0.03 at tempo pace

DRILL Short Stride Run Beginner

Shortening your stride length naturally brings foot contact back under your hips, reducing braking force without disrupting your forefoot strike pattern.

A focused drill to eliminate overstriding by practising landing with your foot beneath your hips.

Step-by-step instructions

Watch drill

Stride Asymmetry Minor

A 9.7% contact time difference between left and right sides is borderline and worth monitoring. At moderate fatigue (5/10) this asymmetry may increase under higher effort and is associated with elevated risk of compensatory loading over longer runs.

`Measured: 9.7% contact time difference` `Reference: < 8% symmetry difference`

DRILL Single-Leg Balance Beginner

Improving single-leg stability and proprioception on your weaker side directly addresses the root cause of contact time asymmetry.

Builds the hip stability needed to prevent hip drop during the single-leg stance phase of running.

Step-by-step instructions
